

A browser campaign can run for days

Magpi keeps it moving at a cost small teams can live with

Open-source desktop browser worker

Recurring browser work

Operators keep redoing the same browser chores because the work spans sites, takes time, and usually has one human-only exception.

A dozen tabs

One marketing operator described gathering daily numbers across so many tools that the spreadsheet looked like a ransom note.

- 01 **Price sweep**
Check priority competitor SKUs and flag changes
- 02 **Morning report**
Collect ad, analytics, and review data
- 03 **Listing check**
Find sold-but-live marketplace inventory
- 04 **SEO upkeep**
Gather recurring audit and link issues

The reset problem

A browser campaign loses value when the person must return to restart the work after every exception.

10 hours of work

can turn into many short sessions when a credit limit, a login, or a decision breaks the chain

The real cost includes the attention that the campaign keeps pulling back

Magpi campaign control

The worker keeps the job alive. A person joins for the exception, then leaves the campaign to continue.

The human step becomes a short review, not an indefinite handoff

A low-cost worker with a frontier coach

The harness separates repeated browser work from the intelligence that supervises quality.

LOW-COST WORKER

Harvests the web

Handles repeatable pages, forms, and data collection across the campaign.

MAGPI HARNESS

Keeps the campaign alive

Retains state, manages the next step, and routes exceptions without restarting the campaign.

FRONTIER COACH

Raises the quality bar

Reviews output at checkpoints, spots failure patterns, and guides the lower-cost worker when the campaign needs stronger reasoning.

Magpi spends frontier-model budget on supervision and correction, rather than on every browser step.

Long campaign comparison

Magpi does not claim that ChatGPT Work or Claude cannot automate browser work. It concentrates on the operating model around the run.

	MAGPI	CHATGPT WORK	CLAUDE
Primary job	Recurring browser campaigns	Multi-step employee work	Buildable computer-use agents
Cost model	Low-cost work, frontier review at checkpoints	Contract-specific credits	Token and action economics
Long run	Harness holds state and resumes after review	Workspace controls apply	Builder manages loop and state
Quality control	Frontier coaching at checkpoints	Workflow and model dependent	Builder chooses the reviewer

Magpi uses expensive reasoning only where it improves the campaign

Early buyers

Small teams already paying with their time

Competitor price sweeps

A daily read of priority products. The owner reviews meaningful changes instead of manually opening every product page.

Marketing morning pulse

A compact daily report from fragmented dashboards, ready for a person to assess and act on.

Read first. Write only after human approval.

Delegated harvesting multiplies output

Magpi gathers and flags the web work. The business person keeps the judgment, the customer context, and the final action.

SERVICE BUSINESS

5x

**more account briefs
ready for review**

20 to 100 target accounts each week

Magpi harvests company facts, role changes, and CRM gaps. The owner qualifies the shortlist and starts the conversation.

E-COMMERCE OPERATOR

10x

**more priority SKUs
under watch**

50 to 500 product pages each day

Magpi harvests price, stock, and listing signals. The operator reviews the exception queue and protects margin faster.

Illustrative operating targets, not customer results. Output depends on the workflow, websites, and review standard.

Product path

Magpi starts local, then removes deployment friction, then helps teams reuse what they teach it.

Browser work becomes a campaign

A low-cost worker does the harvest. Magpi holds the state and brings in frontier coaching when the work needs it.

Campaign output comparable to frontier-model runs, with far less frontier-model spend

MAGPI
